

What is the function of driving the optocoupler module

Overview

An optocoupler, also known as an opto-isolator or photocoupler, transfers electrical signals between circuits using light. This unique design ensures that the two circuits remain electrically isolated. Optocouplers are very useful when you need to isolate different sections of a circuit, for example in power. Optocouplers, also known as opto-isolators, use infrared light to transfer electrical signals between two electrically isolated circuits and are commonly classified by their photosensitive output device. What is an Optocoupler?

An optocoupler (also called an opto-isolator, photo-coupler, or optical. The Schmitt inverter at the output performs several functions; it ensures that the output conforms to HCT voltage and current specifications, it also provides very fast rise and fall times for the output, and corrects the signal inversion caused by the phototransistor being operated in common. An optocoupler, also known as photocoupler or opto-isolator, is a device which can transfer an electrical signal across two galvanically-isolated circuits by way of optical coupling.
